GROUP PROJECT VIDEO RECORDING GUIDE

For Harsh, Ankit, Sam and Vraj

Cybersecurity Education and Awareness Training Application | COMP6900 | 7 November 2026

Purpose

Help the team combine individual recordings into a coherent 15-20 minute demonstration. The assignments below are suggested speaking sections; confirm them with each member. Each person should explain their actual contribution in their own words.

Speaker	Suggested content	Time
Harsh	Introduction, learner interface, modules, progress, feedback, responsive display, dashboard and notifications. Recording completed.	3-5 min
Ankit	System architecture, local SQLite database, data relationships and setup.	4-5 min
Sam	Assessment workflow, saved attempts, marking, results and 90% pass rule.	4-5 min
Vraj	Roles, training administration, two-factor authentication, testing and limitations.	4-5 min

Group coordination

Check the combined runtime after adding introductions and transitions. Avoid repeating Harsh's complete frontend walkthrough; use short examples that support your technical explanation. Each member should add one truthful sentence about work they personally did.

The application is a coursework prototype. Demonstrate it using test data, and use the current version of the application shown in your recording.

ANKIT | Architecture and database

Suggested length: 4-5 minutes | Confirm this speaking allocation with the team

1. Explain the architecture (about 1 minute)

Show: Show the architecture diagram or one slide: Browser -> ASP.NET Core Razor Pages -> EF Core -> local SQLite. Mention ASP.NET Core Identity for accounts and roles.

> **Suggested words:** The browser displays the learning interface. ASP.NET Core handles page requests and application logic. Entity Framework Core connects the application to a local SQLite database. ASP.NET Core Identity manages authentication and account-related features.

2. Explain what the database stores (about 1-2 minutes)

Show: Show a schema diagram or DB Browser for SQLite in Database Structure view. Point to table names, not account records.

> **Suggested words:** The database stores users and roles, module enrolments, section progress, schedules, question banks, assessment attempts and answers. For example, an assessment attempt belongs to a learner and a question bank; its answers record the options the learner selected.

Useful table examples: AspNetUsers, AspNetRoles, SectionProgressEntries, ModuleEnrollments, AssessmentBanks, AssessmentQuestions, AssessmentOptions, AssessmentAttempts and AssessmentAnswers.

3. Explain setup and data flow (about 1 minute)

> **Suggested words:** The app uses a local SQLite file. Entity Framework migrations create and update its schema. Question-bank data is seeded from the project JSON file. When a learner completes a section or submits an assessment, the application saves the relevant records to the database.

4. Contribution and handoff (about 30 seconds)

> **Suggested words:** My contribution to the project was [describe your own actual work and evidence]. Next, Sam will explain the assessment process.

Recording note: Keep emails, password hashes, authentication secrets and real learner records out of the recording. Do not share the local database file.

SAM | Assessment and feedback

Suggested length: 4-5 minutes | Use a disposable learner account

1. Introduce the assessment journey (about 1 minute)

Show: Open an eligible module and show its assessment entry point. All seven sections must be marked complete first.

> **Suggested words:** After a learner completes the module sections, the knowledge assessment becomes available. The application selects a published question bank and creates or resumes the learner's unfinished attempt for that module.

2. Show answer saving and server marking (about 1-2 minutes)

Show: Select an option, leave the page and return through the module or assessment history. Show that the answer is restored. If prepared in advance, submit a controlled attempt.

> **Suggested words:** The learner's selected answers are saved against their attempt. On submission, the server marks the objective questions and stores the score and feedback. The assessment history allows the learner to continue an unfinished attempt or review a completed result.

3. Explain results, retries and the pass rule (about 1 minute)

Show: Show a prepared result and its explanations. If useful, show a failed attempt and a separate passed state.

> **Suggested words:** The default pass mark is 90 percent. A learner can try again after a score below that threshold. Once the learner passes, further attempts for that module are locked, and the module shows the best completed score. The current feedback page shows all choices, highlighting the correct option in green and an incorrect selected option in red, with an explanation.

4. Handling missing links and handoff (about 30 seconds)

> **Suggested words:** An unavailable assessment or page shows a recovery page with links back to modules and home. My contribution was [describe your own actual work]. Next, Vraj will cover administration, account security and evaluation.

Team decision: The current build shows correct options after a failed attempt. Any proposed change to that feedback policy should be agreed before describing a different behaviour.

VRAJ | Management, account security and evaluation

Suggested length: 4-5 minutes | Use test accounts and prepared examples

1. Roles and training management (about 1 minute)

Show: Show an admin or assigned module owner account, Manage training, an enrolment and a schedule. Avoid exposing personal emails.

> **Suggested words:** The application supports learners, module owners and administrators. An administrator can assign module owners. Owners manage the modules assigned to them, including enrolling learners and setting assessment due dates and repeat intervals.

2. Two-factor authentication (about 1 minute)

Show: Open Account security with a disposable account. Explain the setup screen or show that two-factor authentication is enabled. Keep QR codes, setup keys, one-time codes and recovery codes off screen.

> **Suggested words:** A learner can use an authenticator app as a second factor in addition to their password. After setup, the sign-in process asks for a code from that authenticator. Two-factor authentication is available as an option; it is not mandatory for every account in this prototype.

3. Notifications and testing (about 1 minute)

> **Suggested words:** The notifications page shows a signed-in learner's assignments, due dates and status. The reminders are calculated when the page is opened. They are not background email or push notifications. The last completed automated test run reported 31 passing tests; the team should rerun and report the actual result for the final version.

4. Limitations, contribution and closing (about 1 minute)

> **Suggested words:** The current system is a coursework prototype using local SQLite. Production hosting, production email, operational backups and a full privacy and security review remain future work. My contribution was [describe your own actual work]. Together, the project demonstrates a practical workplace learning and assessment workflow. Thank you.

Before submitting: Rehearse transitions, confirm each contribution, combine the clips to 15-20 minutes, and check the final video and audio.
